Table 2. Ohio Counties Ranked by Median Age

Table 3. Ohio Counties Ranked by Percent 65 Years and Over

Table 4. Ohio Counties Ranked by Sex Ratio

Table 5. Ohio Counties Ranked by 65 and Over Sex Ratio

Table 6. Ohio Counties Ranked by Youth Dependency Ratio

Table 7. Ohio Counties Ranked by Aged Dependency Ratio

Table 8. Ohio Counties Ranked by Total Dependency Ratio

Table 9. Age and Sex Distribution for All Ohio Counties

INTRODUCTION

This publication provides data on age and sex composition for Ohio counties. In addition to absolute numbers and percentages, several indices and ratios have been calculated to assist the user in interpreting the data.

Age is one of the most relevant of all population characteristics. It is the basis for understanding many of the conditions and events in an area. For example, knowing the birth rate of an area tells us little unless we know the underlying age structure. One would naturally expect a suburban community with many young couples of childbearing age to have a higher birth rate than a retirement community. Other age related concerns might include school enrollment, new housing demand, entry into the labor force, new family formation and retirement related concerns. The nation's current concern for Social Security, for example, is in large part the result of increasing numbers of people in the middle and older age groups combined with fewer numbers entering the labor force.

DEFINITIONS

None of the indices or ratios presented here is especially complex. However, knowledge of how they are computed is essential to their interpretation and understanding their relevance.

1. Median Age -- This is a simple average which is the mid-point of all ages in the group. For example, the state median age is 29.9 which means that half of the population is older than 29.9 years and half are younger than 29.9.
2. Percent 65 Years and Over -- This is a measure of the proportion of the population in the older age groups. In general, the higher the percentage of the elderly in a population, the more of the total resources of that area that must be expended for their support. General welfare, retirement facilities and medical care are examples of the types of expenditures that need to be provided. The aged dependency ratio (explained later) is an alternative measure of this effect.
3. Sex Ratio -- This is an indicator of the balance (or imbalance) between the number of males and females in the population. It is computed by dividing the number of males by the number of females and multiplying by 100. Thus, the interpretation of the state sex ratio of 93.5 would be that there are 93.5 males for every 100 females in Ohio. A ratio of 100 would indicate an even balance between the sexes, while a ratio in excess of 100 would mean that there are more males than females in the area.
4. Sex Ratio 65 Years and Over -- This is the sex ratio of the elderly and is calculated the same way as the total sex ratio except that only the population over 65 years is included. This ratio is nearly always much lower than the total sex ratio due to the longer life expectancy of females. Currently, females live five to seven years longer than males, on the average. Thus, the

Ohio aged sex ratio of 65.4 indicates that there are 65.4 males over 65 years for every 100 females in that age group.

5. Dependency Ratios -- These are a particularly useful set of ratios which measure the proportion of dependent and productive population in an area. In general, the productive population must provide support for the young and old in an area. For the purposes of these ratios, the young are defined as those under 20 years of age and the aged are those 65 and over. Obviously, there are some youth of 18 and 19 years of age who are self-supporting and many in the over 65 age group are self-sufficient. Nonetheless, these ratios are useful indicators of dependency.

Three dependency ratios are generally calculated. The youth dependency ratio (YDR) is determined by dividing the population 0-19 years by the population 20-64 years and then multiplying by 100. The aged dependency ratio (ADR) is calculated the same way except that the population 65 and over replaces the youth population in the computation. The total dependency ratio (TDR) is simply the sum of the YDR and the ADR. These ratios are interpreted as proportions of the population that are dependent per 100 productive population. Thus, in Ohio the YDR of 57.2 indicates that every 100 productive people in the state must support approximately 57 youth. Similarly, the ADR of 19.1 means that each 100 productive Ohioans provide for 19 elderly. The TDR of 76.3 would be likewise interpreted. Obviously, as the ratios increase, an increase in support would be needed from the population as a whole. Those counties with the highest TDR's can generally expect to be taxed more heavily for schools, children's services, and facilities for the elderly than those with lower TDR's.
